Further Afield

by Rob Harlan

When it's their time to go, most folks would probably prefer to push up daisies in a peaceful, manicured Woodlawn, Green Lawn, or Spring Grove. Some of the more adventurous among us might request their ashes be spread over a lofty crag, an ancient shrine of desert solitude, or perhaps over a tranquil turquoise sea. But when it's my turn to go, it would suit me just fine if they shoved me under the boardwalk at the Magee Marsh Bird Trail.

I'm crazy about the place, and have been for years. It's the crown jewel of Ohio birding, and whether it's known as Magee Marsh, Crane Creek, or simply The Bird Trail, the name is synonymous with Midwestern spring birding at its most delicious. I offer no apologies to other prime Ohio birding sites—I've tried them all, and I do like them. Each has its own uniquely outstanding qualities and rarities bragging rights. But they simply can't stack up against the Bird Trail when it comes to consistent variety and numbers. And if you've been to the Trail on a good day, then I'm preaching to the choir.

I'm probably safe in assuming that most everyone reading this column has visited the Trail at least once or twice, or maybe once a year for many years, or even dozens and dozens of times throughout the years. I'm thankful to say I fall into the last category. Shame on you if you've never birded the Trail; if you fall into *this* category, please take a moment right now to remove five birds (of your choice) from your life list. You may have them back once you've made your first visit. Thank you for your cooperation.

So what makes the Trail so special? There are any number of reasons of course, but some of the most frequently-cited might be: lots of birds, lots of colorful birds, lots of colorful singing birds, and lots of *good* colorful singing birds, all in a delightful lakefront environment and shared with the company of old birding friends. But even more intriguing to me is the fact that we can have all of the above in a comfortable framework of predictability, based on the collective knowledge gained in a century of spring fieldwork. In our instinctive efforts to make order out of seeming chaos, we have come to know what to expect and when, and in what numbers, all with a reasonable degree of accuracy. But each spring always throws in enough wildcards to keep us off balance, to force us constantly to redefine the dimensions of our predictable framework. You can be sure that just as soon as we think we have all the answers, nature will change the questions. But that makes it fun.

This past spring was really no different from most other springs at the Bird Trail. Some individual birds were early, most were on time, and some were late. Some species were in low numbers, most were in expected numbers, and some were more plentiful than usual. And rarities were found. All of which serves to reinforce our framework of predictability. But when boiled down in this manner, it makes spring 2000 seem dry and lifeless, which it most assuredly was not. And so I offer some of my personal reflections regarding the May 2000 Bird Trail season. Let's start on...

May 4—Everything's early! Well, perhaps not everything, but enough things to be of special note...one Cape May, three Blackburnians, one bay-breasted, one blackpoll, three Wilson's, and even a mourning warbler. Plenty of early returnees, all riding

Spring 2000

along the front edge of migration's bell curve. Only Canada and Connecticut were missing from the usual cadre of late-blooming warblers. Plenty of individuals were also accounted for, including 65 yellow and 150 yellow-rumped warblers. The two golden-winged warblers were the only ones I had this season, and I worry that this bird is simply going to become harder and harder to find in the future. A total of 26 warbler species were tallied at the Trail this day, and as it turned out this was my most productive warbler day of the season. Although 4 May is decidedly early for a peak day, the weather patterns leading up to the day (a period of steady northerly winds suddenly changing to southerly) helped to predict that a good day was likely in store. Predicting migration based on weather patterns isn't an exact science, but one can make an educated guess. I guessed right on this one.

May 7—A nice array of 24 warbler species, but flycatchers stole the show this day. Single yellow-bellied, alder, and olive-sided flycatchers tied or beat my earliest spring records for these species. It was indeed a treat to hit the Trail again with birding *maestro* Jon Dunn, and actually be able to prove to him that flycatchers can and do show up before they're allowed. Glad to help, Jon. Right about this date is when I usually expect the peak of warbler migration to begin, and I recorded 18 species in numbers of five or better.

May 8—What do you do when you discover a bird that no one *should* believe? You sneak it into a commentary, that's what. We were almost alone on the Trail this Monday morning, which seemed odd for a peak-season date, weekday or not. So consequently when a bird popped out of the shrubbery a few yards off the Trail, no one else was there to see it with us. And when one is dealing with a bird that might represent a first state record, that's not good. We recognized instantly that the bird appeared most like a gray-checked thrush: a nice bird, but certainly not unexpected. Except this bird was a much warmer brown on the back than any gray-checked thrush I've ever seen around these parts. Its tail was an even brighter rufous than the back, but was never pumped in the habit of a hermit thrush. It had a mostly complete, thin, gray eyering, along with a grayish face and spotted breast. And its bill seemed much too yellow for a typical gray-cheeked. We watched it for several minutes as it perched politely in the open, on the edge of a small bush just off the trail and in good sunlight to boot. And then it flew away.

We alerted several birders we met on the Trail that day to keep their eyes open, but as far as we know, it was never seen again. Our diagnosis? The field marks seemed to best point to a Bicknell's thrush. This recent split from gray-checked thrush nests in the mountains of the far northeastern US and Canada, and winters in the Caribbean, having breeding and wintering habitats entirely segregated from gray-checked. Its song and calls also differ markedly from gray-checked's, and the bird is nowhere particularly common. And as far as we know, it has no business ever being in Ohio.

Why not submit this record to the Ohio Bird Records Committee for a proper peer review? After all, it might be accepted, and become an important part of the historical record. But much more likely, it would not be accepted, for a variety of reasons. And since I'm a voting member of the Committee, I'm already intimately familiar with the conservative stance the Committee *must* take. Some points given for non-acceptance might include: 1) Bicknell's thrush has not established a pattern of vagrancy that might

explain its presence here (a 1933 Ohio specimen we're still trying to sort that record out); 2) no photos; 3) no other observers corroborated the sighting; 4) the small, gray-checked was not noted; 5) no vocalizations were recorded; 6) such a rare species; and 7) identification can be t

All of the above are valid reasons to consider judgment. As a Committee member, I would be it were submitted—and based on the reasoning g tism I'd probably have to cast a "no" vote on my to be correctly identified. And that would be ab head. So here we stand, in rarity limbo. Perhaps nell's thrush isn't so unbelievable for Ohio after might have some significance after all. But, at th to this column.

May 13—International Migratory Bird Day to bird the Trail. Yes, it falls during the tradition weekend the Trail is typically clogged with as m seemed a bit down this year, which made it easie rack up 20 species of warblers, although 16 spec individuals, with 15 northern waterthrushes a no arrive early, hoping to avoid the worst of the cro arrived *very* early. As it turned out, perennial IM miserant Vic Fazio had heard a singing chuck-w long-overdue first record for the Trail. Although to settle for a nifty whip-poor-will in the woods IMBD festivities.

explain its presence here (a 1933 Ohio specimen might represent this species, but we're still trying to sort that record out); 2) no photographs were obtained; 3) no other observers corroborated the sighting; 4) the smaller size of Bicknell's compared to gray-cheeked was not noted; 5) no vocalizations were heard; 6) more details are desired for such a rare species; and 7) identification can be tricky for this species.

All of the above are valid reasons to consider voting against this record in my judgment. As a Committee member, I would be required to vote on this very record if it were submitted—and based on the reasoning given above, in the spirit of conservatism I'd probably have to cast a "no" vote on my own record, even though I believe it to be correctly identified. And that would be about as much fun as a swift kick in the head. So here we stand, in rarity limbo. Perhaps the future will show us that Bicknell's thrush isn't so unbelievable for Ohio after all, and perhaps, in time, this record might have some significance after all. But, at the very least, it helped add extra spice to this column.

May 13—International Migratory Bird Day is not usually one of my favorite days to bird the Trail. Yes, it falls during the traditional peak of migration, but as it's on a weekend the Trail is typically clogged with as many birders as birds. Attendance seemed a bit down this year, which made it easier to slowly roam the boardwalk and rack up 20 species of warblers, although 16 species were represented by five or fewer individuals, with 15 northern waterthrushes a notable exception. We had decided to arrive early, hoping to avoid the worst of the crowds, but apparently we should have arrived *very* early. As it turned out, perennial IMBD big-sitter Tom Bartlett and co-miserant Vic Fazio had heard a singing chuck-will's-widow before dawn, providing a long-overdue first record for the Trail. Although we looked for it after dawn, we had to settle for a nifty whip-poor-will in the woods behind one of the tents set up for the IMBD festivities.

The undisputed star of the day, however, and of the spring for me, was Ohio's second ever painted bunting, a fetching female dining at the feeders of the Sportsmen's Migratory Bird Center for most of the day. Having been out of state for the first Ohio record a few years back, this was a real treat for me, as I'm sure it was for the hordes of other observers present that day. Chalk one up for the good guys.

I'm still at a loss, however, to understand one troubling aspect of what turned out to be one of the Trail's finest rarity days ever. Normally, a confirmed Kirtland's warbler on the trail is BIG news, but most people present this day probably had no idea that a Kirtland's was even present. This particular female had been captured in banding nets at Navarre Marsh, some eight miles down the road from the Trail. To my knowledge, all of the birds on display at the banding tent at Magee had been captured at Navarre and driven over to Magee for banding under public scrutiny. I can understand how this may be beneficial to birds in general (banding demonstrations bring the public closer to the birds, and one hopes they will engender increased concern for bird and habitat protection), but I don't see how this arrangement benefits the individual birds captured for banding. And I certainly can't understand the decision to transport a Kirtland's warbler, a critically Endangered Species, the eight miles so that it might be banded in public. Obviously, any banding-related avian fatality is most unfortunate, but one might at least say that it was offered on the altar of "the interests of science."

Spring 2000

But I'm not sure what interests were served by the decisions made regarding this Kirtland's. Its loss would have been tragic, and verge on criminality, if only morally. As far as I know, it was returned to Navarre and released there, after being banded at Magee.

Some thoughts spring to mind: 1) the bird could have been banded at Navarre and then released there—the public can view dozens of Kirtland's warblers on their breeding grounds just a few hours' drive away in Michigan—as I doubt anyone would want to risk this individual just for the sake of seeing it banded; 2) if no licensed banders were present at Navarre to band it there, the bird could simply have been photographed and released unbanded, thereby eliminating the risks involved in transport to Magee; 3) even worse, the persons operating the nets at Navarre may not have identified the bird as a Kirtland's, and unknowingly sent it along with the other more common species over to Magee. Regardless of the thought-process involved, I was personally greatly disappointed by the decision to transport it to Magee, and as you can probably sense, I remain disgusted with the whole scenario. This diatribe isn't meant to condemn bird banding or bird banders, not by a long shot. Nor is it meant to condemn the good-faith efforts over the years on the part of the banding operation in question. But in this case, questions need to be answered. Honest lapses of judgment happen. Let's hope that's all it was in this case.

May 20—Back to birding as it should be—fun. Twenty-two warbler species were still present but eight were represented by only a single individual. Included in these eight were a late orange-crowned warbler and my only Connecticut warbler for the season. Ten mourning warblers were as expected for the date, given a good migrational push. Ten yellow-bellied flycatchers and five alder flycatchers were also in nice but reasonable numbers, while a summer tanager was an unexpected bonus.

May 24—My last day at the Trail this spring. I usually try to make it at least once during early June, if only to be slowly weaned rather than quit cold-turkey. When birders are outnumbered by supercilious beach-goers on the boardwalk, it is time to move on. Not to be dissuaded, however, two olive-sided flycatchers were still present, and 11 species of warblers lingered bravely in the face of the advancing season. And fittingly, my first-ever female Lawrence's warbler, the recessive hybrid of blue-winged and golden-winged warblers, put in an all-too-brief appearance in the shrubbery at the far west end of the parking lot. She popped quickly into view, peeked around for a bit, and then was gone. A fleeting glimpse—spring migration in a nutshell, I should think.
